

REMOTE MAGNETIC ACTIVATION OF HEARING DEVICES

ABSTRACT OF THE DISCLOSURE

09181533-102398
5 A magnetic switch assembly for hearing devices designed for remote
activation by the user is highly miniaturized with a self-contained latching mechanism. The
switch is activated and deactivated by the user via a hand-held magnet placed in proximity
to the hearing device. The switch assembly includes a miniature reed switch and a miniature
latching magnet affixed directly to one of the reeds or the associated lead wire. Direct
attachment minimizes the air gap between the latching magnet and a reed thus enabling
latching with only an extremely small magnet. The latching magnet produces a magnetic
field of adequate strength to hold the reeds together in electrical contact after the air gap
10 between the reeds is closed by the user's placement of the external hand-held magnet in
proximity thereto. But the latching magnet's field is of inadequate strength for unaided
closure of the air gap between the reeds. Consequently, once the reeds are closed the
latching magnet prevents separation thereof until the reeds are exposed to an external
magnetic field of opposite polarity and sufficient strength to overcome the field produced by
15 the latching magnet.
